

## Visualizing Linear Models:

### An R Bag of Tricks

#### Session 3: Examples & Extensions

Michael Friendly

SCS Short Course

Oct-Nov, 2021

<https://friendly.github.io/VisMLM-course/>

## Today's topics

- MANOVA examples
  - Distinguishing among psychiatric groups
  - Robust MLMs: down-weighting outliers
- Multivariate regression
  - PA tests & ability
  - Canonical correlation
  - MANCOVA & homogeneity of regression
- Homogeneity of (co)variance
  - Visualizing Box's  $M$  test

2

#### Ex: Neuro- & Social-Cognitive measures in psychiatric groups

- A study by Leah Hartman @York examined whether patients classified as 'schizophrenic' or 'schizoaffective' (on DSM-IV) could be distinguished from a normal, control sample on standardized tests in the following domains:
  - **Neuro-Cognitive**: processing speed, attention, verbal learning, visual learning, problem solving
  - **Social-cognitive**: managing emotions, theory of mind, externalizing bias, personalizing bias
- Research questions → MANOVA contrasts
  - Analyze neuro-cog (NC) and social-cog (SC) separately
  - Do the two psychiatric groups differ from the controls?
  - Do the psychiatric groups differ from each other?

See: Friendly & Sigal (2017), Graphical Methods for Multivariate Linear Models in Psychological Research: An R Tutorial  
*The Quantitative Methods for Psychology*, 13, 20-45, <http://dx.doi.org/10.20982/tqmp.13.1.p020>

3

**Schizophrenia** symptoms: Hallucinations, disorganized thinking, delusions, ...  
**Schizoaffective** disorder combines symptoms of schizophrenia with mood disorder (bipolar or depression)

4

# Neuro-cognitive measures

## Data

```
> car::some(NeuroCog)
   Dx Speed Attention Memory Verbal Visual ProbSolv SocialCog Age Sex
14 Schizophrenia 19    9     19    33    24    39    28  44 Female
88 Schizoaffective 27   44     24    33    26    31    36  53 Female
105 Schizoaffective 23   41     42    48    46    29    50  52 Female
114 Schizoaffective 41   53     47    39    30    50    63  32 Female
130 Control        44   25     21    37    32    43    29  43 Male
165 Control        35   35     43    53    57    37    40  30 Male
194 Control        47   40     53    53    40    45    49  55 Female

  diagnostic group ----- neuro-cognitive measures ----- -- ignored --
```

## Questions:

- Do the diagnostic groups differ **collectively** on the neuro-cognitive measures?
- How do group differences relate to **research hypotheses**?
- How many **dimensions** (aspects) are reflected in the differences among means?

5

# Neuro-cognitive measures: Analyses

- Could do a series of univariate ANOVAs
  - car::Anova(NC.mlm1 <- lm (Speed ~ Dx, data=NeuroCog))
  - car::Anova(NC.mlm2 <- lm (Attention ~ Dx, data=NeuroCog))
  - car::Anova(NC.mlm3 <- lm (Memory ~ Dx, data=NeuroCog))
  - ...
- Better: MANOVA test for **all 7 responses together**
  - Anova(NC.mlm = lm(cbind(Speed, Attention, Memory, ...) ~ Dx, data=SocialCog))
- Research hypotheses: test contrasts
  - Dx1: Control - (Schiz + SchizAff)/2 = 0 → linearHypotheses(NC.mlm, "Dx1")
  - Dx2: Schiz - SchAff = 0 → linearHypotheses(NC.mlm, "Dx2")
- Dimensions:
  - Canonical analysis → NC.can <- candisc(NC.mlm); plot(NC.can)
  - Canonical HE plot → heplot(NC.can)
- Tech note: anova() in base R vs. car::Anova
  - anova() uses only Type 1 (sequential) tests, rarely useful; doesn't handle MLM well ✗
  - car::Anova() provides Type 2, 3 (partial) tests; give sensible results for MLMs ✓
  - car::linearHypotheses() gives univariate and multivariate tests of contrasts ✓

6

# Neuro-cognitive measures: MANOVA

```
library(heplots); library(car)
data(NeuroCog, package="heplots")

# fit the MANOVA model
NC.mlm <- lm(cbind(Speed, Attention, Memory, Verbal, Visual, ProbSolv) ~ Dx,
              data=NeuroCog)
Anova(NC.mlm)

Type II MANOVA Tests: Pillai test statistic
  Df test stat approx F num Df den Df Pr(>F)
Dx  2  0.2992  6.8902    12    470 1.562e-11 *** ✓
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

So, the groups differ. But how?

What about the research hypotheses? →

```
> contrasts(NeuroCog$Dx)
      [,1] [,2]
Schizophrenia -0.5  1
Schizoaffective -0.5 -1
Control         1.0  0
```

Dx1: Control - (Schiz + SchizAff)/2 = 0

7

# Neuro-cognitive measures: Contrasts

A simple result: Control ≠ (Schizophrenia ≈ Schizoaffective)

```
> print(linearHypothesis(NC.mlm, "Dx1"), SSP=FALSE)

Multivariate Tests:
  Df test stat approx F num Df den Df Pr(>F)
Pillai      1  0.289  15.9   6  234 2.8e-15 ***
Wilks       1  0.711  15.9   6  234 2.8e-15 ***
Hotelling-Lawley 1  0.407  15.9   6  234 2.8e-15 ***
Roy         1  0.407  15.9   6  234 2.8e-15 ***
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

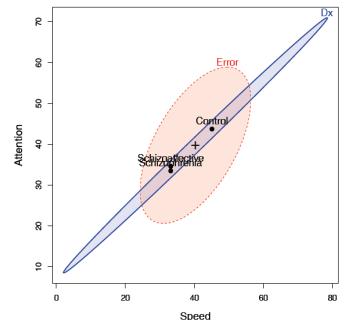

```
> print(linearHypothesis(NC.mlm, "Dx2"), SSP=FALSE)
```

```
Multivariate Tests:
  Df test stat approx F num Df den Df Pr(>F)
Pillai      1  0.006  0.249   6  234  0.96
Wilks       1  0.994  0.249   6  234  0.96
Hotelling-Lawley 1  0.006  0.249   6  234  0.96
Roy         1  0.006  0.249   6  234  0.96
```

8

## Visualize me: in data space

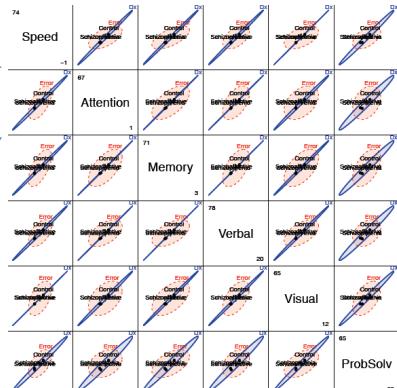

# Bivariate view for any 2 responses:  
`heplot(NC.mlm, var=1:2, ...)`

Wow! All neuro-cog measures highly correlated in group means!

Only 1 dim. of  $\mathbf{H}$  variation

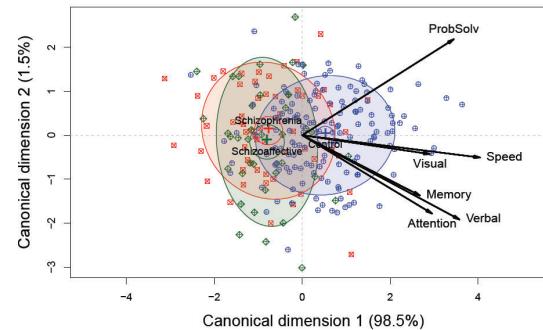

# HE plot matrix: for all responses  
`pairs(NC.mlm, ...)`

9

## Visualize me: in canonical space

- As with biplot, we can visualize MLM hypothesis variation for *all* responses by projecting  $\mathbf{H}$  and  $\mathbf{E}$  into low-rank space.
- Canonical projection:  $\mathbf{Y}_{n \times p} \mapsto \mathbf{Z}_{n \times s} = \mathbf{Y}\mathbf{E}^{-1/2}\mathbf{V}$ , where  $\mathbf{V}$  = eigenvectors of  $\mathbf{H}\mathbf{E}^{-1}$ .
- This is the view that maximally discriminates among groups, ie max.  $H$  wrt  $E$ !

Very simple interpretation

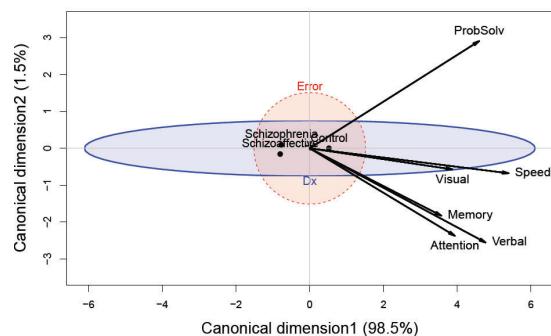

Can1: normal vs. others  
All vars highly + correlated;

Can2: only 1.5%, NS; but  
perhaps suggestive (ProbSolv  
vs. Attention)

10

## Visualize me: canonical HE plots

- Canonical HE plot is just the HE plot of canonical scores,  $(\mathbf{z}_1, \mathbf{z}_2)$  in 2D, or,  $\mathbf{z}_1, \mathbf{z}_2, \mathbf{z}_3$ , in 3D.
- As in biplot, we add vectors to show relations of the  $y_i$  response variables to the canonical variates.
- variable vectors here are **structure coefficients** = correlations of variables with canonical scores.

The multivariate "juicer"

Shows just group means, H ellipse & E ellipse

Variable vectors offer interpretation of Can dimensions.

11

## Social cognitive measures

- These measures deal with the person's perception and cognitive processing of emotions of others
  - Scales: managing emotions, theory of mind, externalizing bias, personalizing bias
- Questions:
  - Do these differentiate normal from patient groups?
  - Can they distinguish between schizophrenic & schizoaffective
  - If so, this could be a major finding.

12

# Social cognitive measures

## Data

```
> car::some(SocialCog)
      Dx MgeEmotions ToM ExtBias PersBias
24  Schizophrenia    32    18     -2    1.00
58  Schizophrenia    32    17      4    0.92
69  Schizophrenia    52    23      2    0.80
85  Schizoaffective   28    12     -5    1.00
99  Schizoaffective   40    22      1    0.36
111 Schizoaffective   51    23      6    0.91
124 Control          51    24     -5    1.00
155 Control          57    28      1    0.30
168 Control          47    32      0    0.77
216 Control          64    31      3    0.69
```

diagnostic group ----- social-cognitive measures -----

## Analyses

Standard MANOVA test:

```
Anova(SC.mlm = lm(cbind(...) ~ DX, data=SocialCog)
```

Test contrasts:

```
linearHypotheses(SC.mlm, "Dx1")
linearHypotheses(SC.mlm, "Dx2")
```

```
> contrasts(SocialCog$Dx)
      [,1] [,2]
Schizophrenia -0.5   1
Schizoaffective -0.5  -1
Control         1.0   0
```

13

```
> data(SocialCog, package="heplots")
> SC.mlm <- lm(cbind(MgeEmotions, ToM, ExtBias, PersBias) ~ Dx,
  data=SocialCog)
> Anova(SC.mlm)
```

Type II MANOVA Tests: Pillai test statistic  
Df test stat approx F num Df den Df Pr(>F)  
Dx 2 0.212 3.97 8 268 0.00018 \*\*\*  
---

Signif. codes: 0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

Test contrasts: Dx1 = Normal vs. Patient; Dx2 = Schizo vs. Schizoaffective

```
> print(linearHypothesis(SC.mlm, "Dx1"), SSP=FALSE)
Multivariate Tests:
```

|        | Df | test stat | approx F | num | Df  | den      | Df  | Pr(>F) |
|--------|----|-----------|----------|-----|-----|----------|-----|--------|
| Pillai | 1  | 0.1355    | 5.212    | 4   | 133 | 0.000624 | *** |        |

```
> print(linearHypothesis(SC.mlm, "Dx2"), SSP=FALSE)
Multivariate Tests:
```

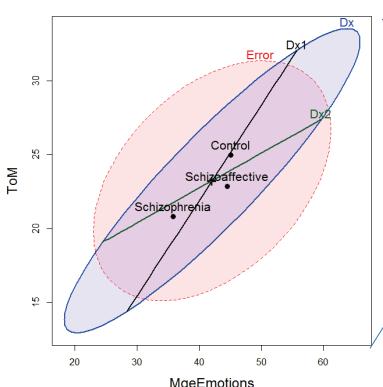

|        | Df | test stat | approx F | num | Df  | den    | Df | Pr(>F) |
|--------|----|-----------|----------|-----|-----|--------|----|--------|
| Pillai | 1  | 0.0697    | 2.493    | 4   | 133 | 0.0461 | *  |        |

14

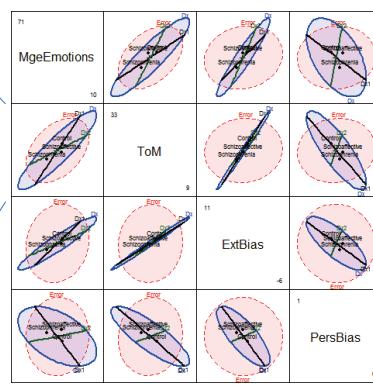

# Visualize me: data space

```
heplot(SC.mlm,
hypotheses=list("Dx1", "Dx2"),...)
```

The groups are ordered Schizo < ScAffective < Control on these measures

```
pairs(SC.mlm,
hypotheses=list("Dx1", "Dx2"),...)
```

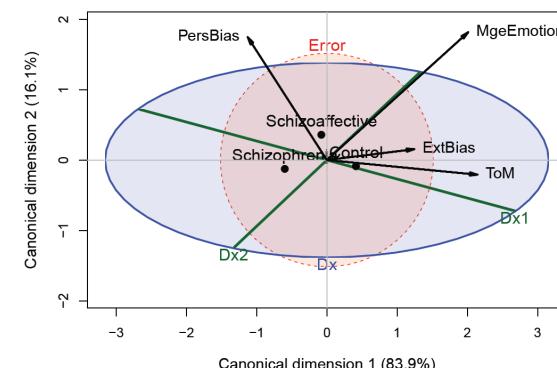

One of these vars is not like the others!

15

# Visualize me: canonical space

Contrasts:

Dx1 : Control vs. patients. Controls > patients on MgeEmotions, ExtBias, ToM  
Dx2 : Schizo vs. schizoaffective.

Can1: group order

Can2: Schizoaffective vs. others

Dx1 suggests ≈ spacing  
Schizo < ScAff < Control

16

## Model checking & remedies

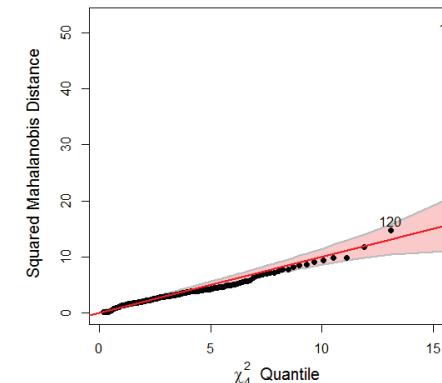

- The MLM assumes residuals are multivariate normal
  - Squared Mahalanobis distances  
 $D^2_M(\mathbf{y}_i) = (\mathbf{y}_i - \bar{\mathbf{y}})^T \mathbf{S}^{-1} (\mathbf{y}_i - \bar{\mathbf{y}}) \sim \chi^2_p$  with  $p$  d.f.
  - a quantile – quantile plot of ordered  $D^2_M(\mathbf{y}_i)$  vs. quantiles of  $\chi^2_p$  should plot as straight line
  - Outliers are readily apparent
  - plots: heplots::cqplot()
- Influence plots
  - mvinfluence::influence() calculates multivariate analogs of influence measures

17

## Social cog: cqplot

heplots::cqplot() creates a chi-square QQ plot from a MLM

```
cqplot(sc.mlm, id.n=2)
```

One observation appears as an extreme outlier.

This was a case w/ ExtBias = -33, but valid range = (-10, +10)

Refitting w/o case 15:  
Overall & DX1 tests still OK ☺  
Dx2 test:  $p=0.074$ , now NS ☺

18

## Social cog: Influence

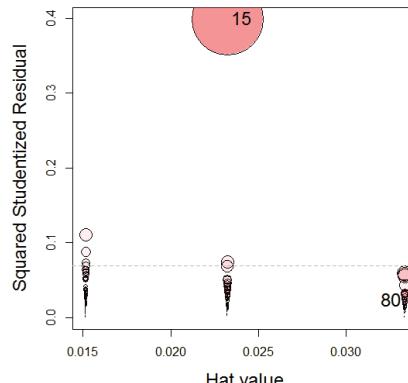

mvinfluence::influencePlot() creates a multivariate analog of an influence plot

```
>library(mvinfluence)
>influencePlot(sc.mlm, ...)

      H      Q     CookD      L      R
15 0.0233 0.3985 0.4202 0.0238 0.4080
80 0.0333 0.0233 0.0352 0.0345 0.0241
```

Case 15 stands out as hugely influential

The 3 columns of circles correspond to the 3 groups

19

## Robust MLMs

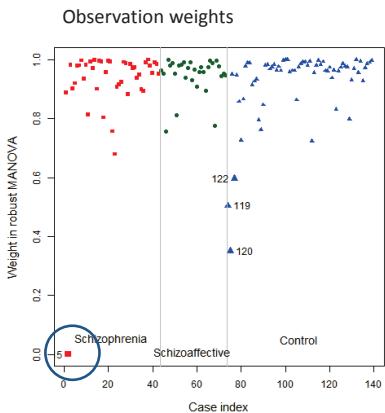

- Robust methods for univariate LMs are now well-developed and implemented
  - proper SEs, CIs and hypothesis tests
- Analogous methods for multivariate LMs are a current hot research topic
- The heplots package now provides `robmlm()` for the fully general MLM (MANOVA, MMReg)
  - Uses simple M-estimator via IRLS
  - Weights: calculated from Mahalanobis  $D^2$ , a robust covariance estimator and weight function,  $\psi(D^2)$
- Downside: SEs,  $p$ -values only approximate

$$D^2 = (\mathbf{Y} - \bar{\mathbf{Y}})^T \mathbf{S}_{\text{robust}}^{-1} (\mathbf{Y} - \bar{\mathbf{Y}}) \sim \chi^2_p$$

20

## Robust MLMs

```
SC.rlm <- robmIm(cbind( MgeEmotions, ToM, ExtBias, PersBias) ~ Dx,
  data=SocialCog)
```

Approx test of Dx2 in robust model

```
> print(linearHypothesis(sc.rlm, "Dx2"), SSP=FALSE)
Multivariate Tests:
          Df  test stat approx F num  df den  df Pr(>F)
Pillai   1  0.069    2.44      4   132  0.05 *
Wilks    1  0.931    2.44      4   132  0.05 *
...
```

21

## Robust MLMs: Pottery data

- Chemical composition of ancient pottery found at four sites in Great Britain

- Sites: AshleyRails, Caldicot, IsleThorns, Llanedlyn
- Measures: Al Fe Mg Ca Na

- Analyses:

- standard MANOVA `lm(cbind(Al, Fe, Mg, ...) ~ Site, data=Pottery)`
- robust MANOVA `robmIm(cbind(Al, Fe, Mg, ...) ~ Site, data=Pottery)`

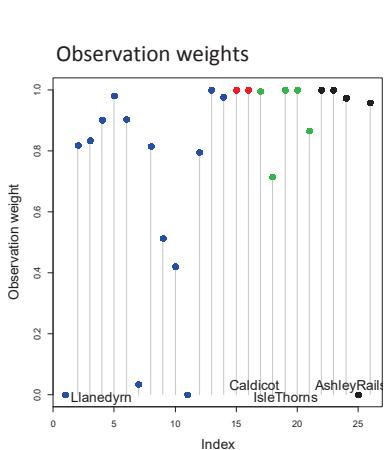

- Data:

```
> car::some(Pottery)
  Site Al  Fe  Mg  Ca  Na
2  Llanedlyn 13.8 7.08 3.43 0.12 0.17
14 Llanedlyn 12.5 6.44 3.94 0.22 0.23
17 IsleThorns 18.3 1.28 0.67 0.03 0.03
18 IsleThorns 15.8 2.39 0.63 0.01 0.04
21 IsleThorns 20.8 1.51 0.72 0.07 0.10
22 AshleyRails 17.7 1.12 0.56 0.06 0.06
23 AshleyRails 18.3 1.14 0.67 0.06 0.05
```

22

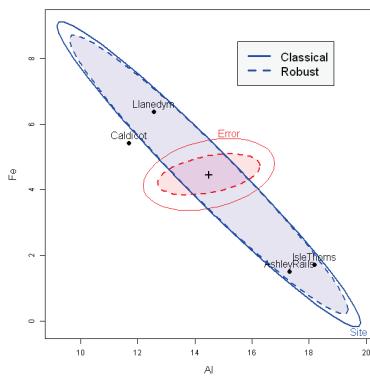

## Robust MLMs: Pottery data

```
> pottery.mod <- lm(cbind(Al, Fe, Mg, Ca, Na)~Site, data=Pottery)
> pottery.rmod <- robmIm(cbind(Al, Fe, Mg, Ca, Na)~Site, data=Pottery)
```

residual E ellipse shrinks a lot

overlaid HE plots

23

## MMRA example: PA tasks & ability

- Rohwer data from Timm (1975)
- How well do paired associate (PA) tasks predict performance on measures of aptitude & achievement in kindergarten children?

- Samples: 69 children in two groups (schools): 'Lo' | 'Hi' SES

- Outcomes (Y):

- Scholastic aptitude test (SAT)
- Peabody picture vocabulary test (PPVT)
- Raven progressive matrices (Raven)

- Predictors (X): Scores (0–40) on PA tasks where the stimuli were:

  - named (n), still (s), named-still (ns), named-action (na), sentence-still (ss)

```
> data("Rohwer", package="heplots")
> car::some(Rohwer, n=5)
  group SES SAT PPVT Raven n  s ns na ss
8     1 Lo   8  68    8 0  0 10 19 14
9     1 Lo   49  74   11 0  0 7 16 13
17    1 Lo   19  66   13 7 12 21 35 27
52    2 Hi   38  66   14 0  0 3 16 11
66    2 Hi   8   55   16 4  7 19 20 13
```

Having a group factor makes the analysis more complicated (MANCOVA)

Start with analysis of the Hi SES group

24

# Why not univariate models?

```
rohwer.mod1 <- lm(SAT ~ n + s + ns + na + ss, data = Rohwer2)
rohwer.mod2 <- lm(PPVT ~ n + s + ns + na + ss, data = Rohwer2)
rohwer.mod3 <- lm(Raven ~ n + s + ns + na + ss, data = Rohwer2)
```

```
library(stargazer)
stargazer(rohwer.mod1, rohwer.mod2, rohwer.mod3, type="text", ...)
```

| Univariate regression models for Rohwer data |                     |       |        |
|--|---------------------|-------|--------|
|  | Dependent variable: |       |        |
|  | SAT                 | PPVT  | Raven  |
| n  | 3.26*               | 0.07  | 0.06   |
| s  | 3.00                | 0.37  | 0.49** |
| ns   | -5.86***            | -0.37 | -0.16  |
| na   | 5.67***             | 1.52* | 0.12   |
| ss   | -0.62               | 0.41  | -0.12  |
| R2   | 0.56                | 0.35  | 0.31   |
| F Statistic (df = 5; 26)                     | 6.54***             | 2.85* | 2.32   |

Note: \*p<0.05; \*\*p<0.01; \*\*\*p<0.001

25

Results are disappointing

- Only model for SAT highly signif.
- Only a few coeffs. signif. ≠ 0

# MANOVA tests

```
> rohwer.mlm <- lm(cbind(SAT, PPVT, Raven) ~ n + s + ns + na + ss, data=Rohwer2)
> Anova(rohwer.mlm)
```

| Df | test | stat  | approx F | num Df | den Df | Pr(>F)    |
|----|------|-------|----------|--------|--------|-----------|

---  
signif. codes: 0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

Much better!

- Multivariate tests:
- pool evidence for all Ys
  - take correlations of Ys into account

Can also test overall hypothesis,  $H_0: \mathbf{B} = \mathbf{0}$  (all coeffs = 0)

```
> print(linearHypothesis(rohwer.mlm,
+                         c("n", "s", "ns", "na", "ss")), SSP=FALSE)
```

Multivariate Tests:

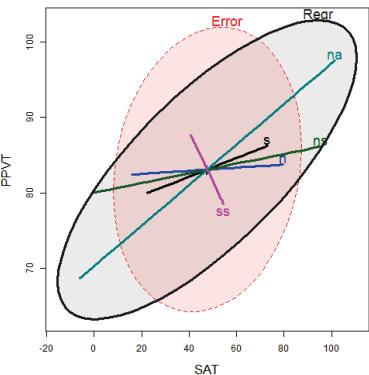

| Df               | test | stat   | approx F | num Df | den Df | Pr(>F)       |
|------------------|------|--------|----------|--------|--------|--------------|
| Pillai           | 5    | 1.0386 | 2.753    | 15     | 78.00  | 0.001912 **  |
| Wilks            | 5    | 0.2431 | 2.974    | 15     | 66.65  | 0.001154 **  |
| Hotelling-Lawley | 5    | 2.0615 | 3.115    | 15     | 68.00  | 0.000697 *** |
| Roy              | 5    | 1.4654 | 7.620    | 5      | 26.00  | 0.000160 *** |

Strongly reject  $H_0$  by all criteria

26

# Visualize me!

```
cols <- c("red", "blue", "black", "darkgreen", "darkcyan", "magenta", "gray20")
hyp <- list("Regr" = c("n", "s", "ns", "na", "ss")) # Test of B = 0
heplot(rohwer.mlm,
       hypotheses = hyp,
       fill=TRUE, fill.alpha=0.1, col=cols, lwd=c(1,3))
```

Each predictor gives a 1 df test  $\rightarrow \mathbf{H}_i$  ellipse is a line  
 $\mathbf{E}$  here is a 3D ellipsoid ( $\text{rank}(\mathbf{E}) = \min(p, q)$ )

Interpretation:

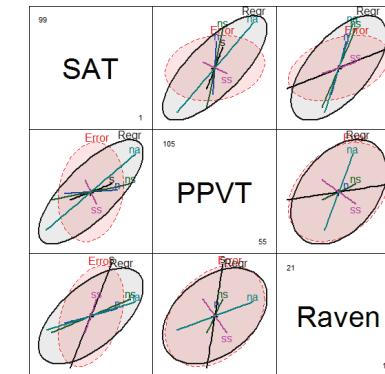

- Any  $\mathbf{H}_i$  ellipse that protrudes outside  $\mathbf{E}$  ellipse is significant by Roy's test
- Length of each  $\mathbf{H}_i$  line  $\approx$  strength of association
- Orientation of each  $\mathbf{H}_i$  line shows relation of  $X_i$  to the two  $Y_j$  responses shown.

27

# pairs.mlm() plot

View all pairwise HE plots

```
pairs(rohwer.mlm, hypotheses=hyp,
      col=cols, fill=TRUE, fill.alpha=0.1, ...)
```

Can now understand more subtle aspects

SAT is best predicted overall, but relation with PA tests varies  
The na & ns tasks are strongest for SAT

Raven is weakly predicted

28

## Canonical correlations

For quantitative (X, Y) data, canonical correlation analysis is an alternative to MMRA  
It finds the weighted sums of the Y variables most highly correlated with the Xs

```
> X <- Rohwer2[, 6:10] # X variables for High SES students
> Y <- Rohwer2[, 3:5] # Y variables for High SES students
> (cc <- cancor(X, Y, set.names=c("PA", "Ability")))

Canonical correlation analysis of:
      5 PA variables: n, s, ns, na, ss
      with    3 Ability variables: SAT, PPVT, Raven

      CanR CanRSQ Eigen percent   cum
1 0.7710 0.5944 1.4654 71.080 71.08 *****
2 0.5465 0.2987 0.4259 20.659 91.74 *****
3 0.3815 0.1455 0.1703 8.261 100.00 **

Test of H0: The canonical correlations in the
current row and all that follow are zero

      CanR LR test stat approx F numDF denDF Pr(> F)

Two dimensions  
acct for 91.7% of  
(X,Y) association

Only Can1 is  
significant

29

## Visualize CCA in HE plot

```
cols <- c("red", "blue", "black", "darkgreen", "darkcyan",
         "magenta", "gray20")
heplot(cc, hypotheses=list("na+ns"=c("na", "ns")),
       fill = TRUE, fill.alpha=0.1, col=cols,
       label.pos = c(3, rep(1.5), .1),
       cex=1.4, var.cex=1.25, var.lwd=3, var.col="black")
```

Residuals are uncorrelated in canonical space

H ellipses for X terms same as in ordinary HE plots – outside E ellipse iff signif. by Roy's test

Variable vectors for Ys: correlations with  
canonical variables Ycan1, Ycan2

- SAT & PPVT: mainly Ycan1
- Raven: more aligned with Ycan2

30

## MANCOVA & homogeneity of regression

- With a group variable (SES) can test differences in means (intercepts)
  - rohwer.mod <- lm(cbind(SAT, PPVT, Raven) ~ SES + n + s + ns + na + ss, data=Rohwer)
  - This assumes that slopes (B) are the **same** for both groups (homogeneity of regression)
- Can test for equal slopes by adding interactions of SES with Xs
  - rohwer.mod1 <- lm(cbind(SAT, PPVT, Raven) ~ SES \* (n + s + ns + na + ss))
- Or, fit separate models for each group

```
rohwer.ses1 <- lm(cbind(SAT, PPVT, Raven) ~ n + s + ns + na + ss,
                    data = Rohwer, subset = SES == "Hi")
rohwer.ses2 <- lm(cbind(SAT, PPVT, Raven) ~ n + s + ns + na + ss,
                    data = Rohwer, subset = SES == "Lo")
```

31

## MANCOVA

Fit the MANCOVA model & test hypotheses

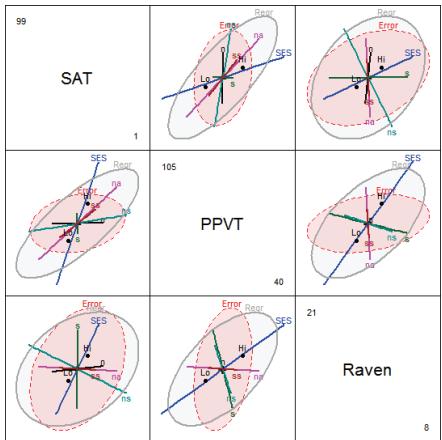

```
> rohwer.mod <- lm(cbind(SAT, PPVT, Raven) ~ SES + n + s + ns + na + ss,
+                     data=Rohwer)
> Anova(rohwer.mod)

Type II MANCOVA Tests: Pillai test statistic
  DF test stat approx F num Df den Df Pr(>F) SES: diff in means
SES  1    0.379    12.18      3    60  2.5e-06 ***
n   1    0.040     0.84      3    60   0.4773
s   1    0.093     2.04      3    60   0.1173
ns  1    0.193     4.78      3    60   0.0047 **
na  1    0.231     6.02      3    60   0.0012 **
ss  1    0.050     1.05      3    60   0.3770
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

32

## Visualize effects

```
pairs(rohwer.mod,
hypotheses=list("Regr" = c("n", "s", "ns", "na", "ss")),
fill=TRUE, fill.alpha=0.1)
```

The SES effect is positive for all Y variables  
Hi SES group > Lo SES group

33

## Fit model with interactions

Fit heterogeneous regression model with SES interactions

```
> rohwer.mod1 <- lm(cbind(SAT, PPVT, Raven) ~ SES * (n + s + ns + na + ss),
+ data=Rohwer)
> Anova(rohwer.mod1)

Type II MANOVA Tests: Pillai test statistic
   Df test stat approx F num Df den Df Pr(>F)
SES    1   0.391   11.78     3     55 4.5e-06 ***
n     1   0.079   1.57     3     55 0.20638
s     1   0.125   2.62     3     55 0.05952 .
ns    1   0.254   6.25     3     55 0.00100 *** 
na    1   0.307   8.11     3     55 0.00015 *** 
ss    1   0.060   1.17     3     55 0.32813
SES:n  1   0.072   1.43     3     55 0.24417
SES:s  1   0.099   2.02     3     55 0.12117
SES:ns 1   0.118   2.44     3     55 0.07383 .
SES:na 1   0.148   3.18     3     55 0.03081 *
SES:ss 1   0.057   1.12     3     55 0.35094
---
Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

OK, as expected

Hmm ???

34

## Test interactions

Can test all interactions **simultaneously** with linearHypothesis()  
Do I need any interaction terms?

I use a 'grep' trick here to find the names of coefficients like 'SES:' containing a ':'

```
> coefs <- rownames(coef(rohwer.mod1)) # store coefficient names in a vector
> print(linearHypothesis(rohwer.mod1,
+                         coefs[grep(":", coefs)]), SSP=FALSE)

Multivariate Tests:
   Df test stat approx F num Df den Df Pr(>F)
Pillai      5   0.4179   1.845    15  171.0 0.03209 *
Wilks       5   0.6236   1.894    15  152.2 0.02769 *
Hotelling-Lawley  5   0.5387   1.927    15  161.0 0.02396 *
Roy         5   0.3846   4.385     5   57.0 0.00191 **
---
signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

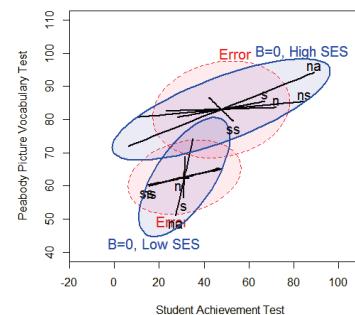

Evidence shows that **some** slopes differ for Hi/Lo SES

35

## Fit separate models

Fitting a model for each group allows all slopes to differ  
Also allows within-group covariances to differ

```
rohwer.ses1 <- lm(cbind(SAT, PPVT, Raven) ~ n + s + ns + na + ss,
                     data = Rohwer, subset = SES == "Hi")
rohwer.ses2 <- lm(cbind(SAT, PPVT, Raven) ~ n + s + ns + na + ss,
                     data = Rohwer, subset = SES == "Lo")
```

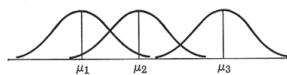

For SAT & PPVT:

- means higher for Hi SES
- within-group covariance larger for Hi SES
- slopes of predictors smaller for Hi SES  
→ SAT more important for this group.

36

## Homogeneity of (co)variances

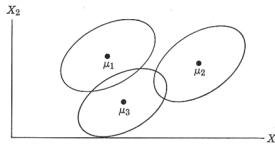

- ANOVA assumes equality of residual variances

$$\sigma_1^2 = \sigma_2^2 = \dots = \sigma_g^2$$

Levine's test: ANOVA of  $z_{ij} = |y_{ij} - \bar{y}_i|$

- MANOVA: assumes equality of covariance matrices

$$\Sigma_1 = \Sigma_2 = \dots = \Sigma_g$$

Box's M test:  $M = (N - g) \ln |\mathbf{S}_p| - \sum_{i=1}^g (n_i - 1) \ln |\mathbf{S}_i|$   
 $-2 \ln(M) \sim \chi^2_{df}$

See: <http://www.datavis.ca/papers/EqCov-TAS.pdf>

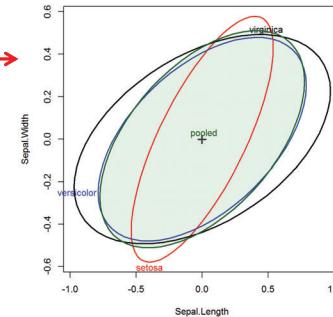

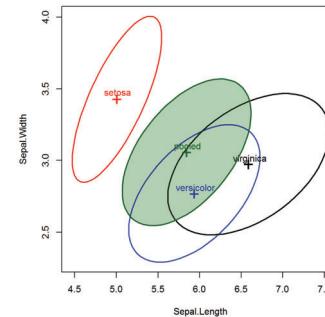

37

## Visualizing covariance matrices

Visualize covariance ellipses in data space  
 Center to see pure differences in size & shape

```
covEllipses(iris[,1:2], iris$Species, ...)  

covEllipses(iris[,1:2], iris$Species, center=TRUE, ...)
```

38

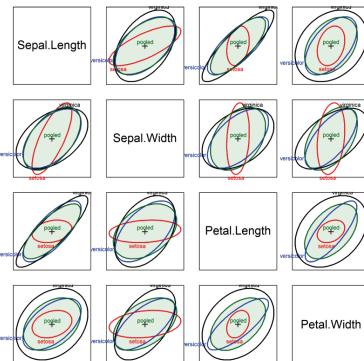

## View all pairs

```
covEllipses(iris[,1:4], iris$Species,  

center=TRUE, variables=1:4, ...)
```

In all cases, **setosa** stands out as different from the others

- sometimes correlation differs
- sometimes smaller variance(s)

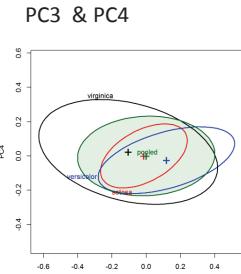

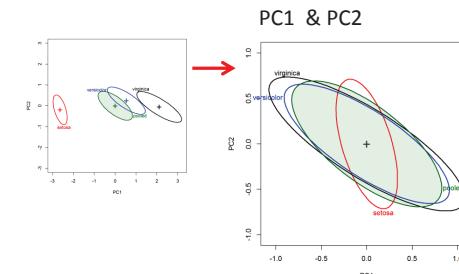

39

## Visualize in PCA space

PCA projects the data into an orthogonal space accounting for maximum variance  
 Covariance ellipses show the differences among groups in this space

Surprisingly, the **small** dimensions contribute largely to Box's M test.

```
iris.pca <- prcomp(iris[,1:4])  

covEllipses(iris.pca$x, iris$Species, ...)  

covEllipses(iris.pca$x, iris$Species, center=TRUE, ...)
```

```
covEllipses(iris.pca$x, iris$Species, center=TRUE,  

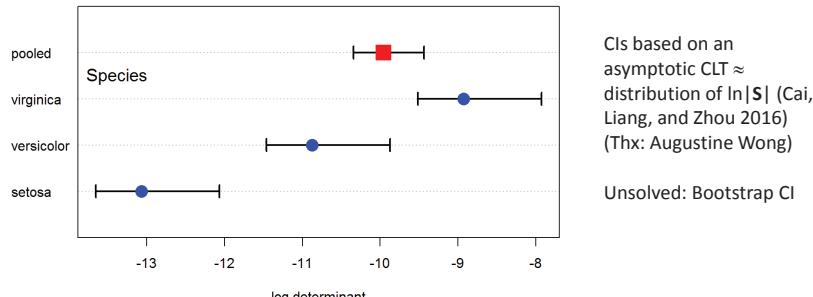

variables=3:4, ...)
```

40

## Visualizing Box's M test

Box's test is based on a comparison of the log  $|S_i|$  relative to log  $|S_p|$ : **plot them!**

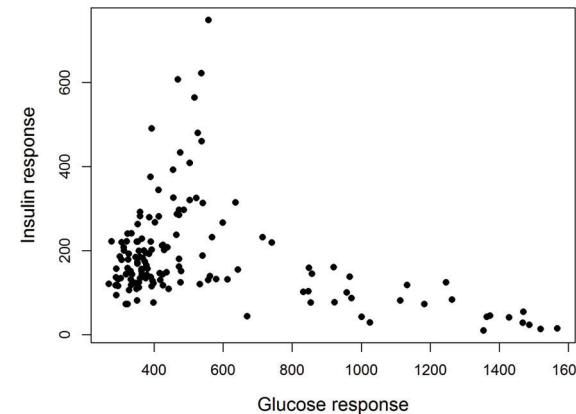

```
iris.boxm <- boxM(iris[, 1:4], iris[, "Species"])
plot(iris.boxm, gplabel="Species")
```

41

## Diabetes data: 2D mystery

Reaven & Miller (1968) found a peculiar "horse shoe" result in analysis of data on the relationship of blood glucose levels and production of insulin in patients with varying degrees of hyperglycemia

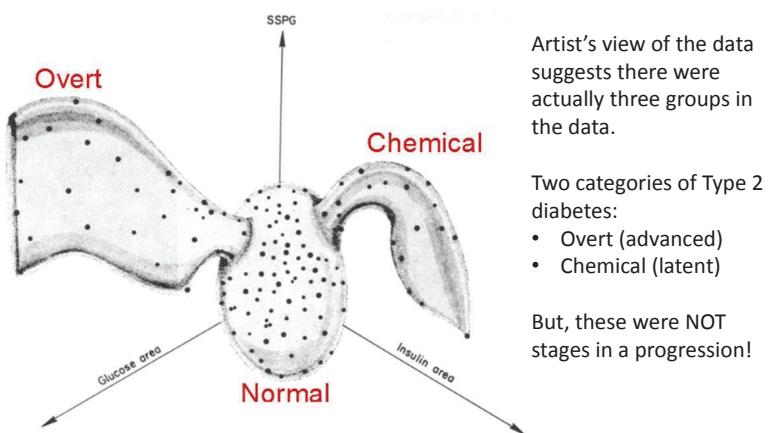

In a 2D plot this was a medical mystery.

What could be the explanation?

42

## Diabetes data: 3D clarity

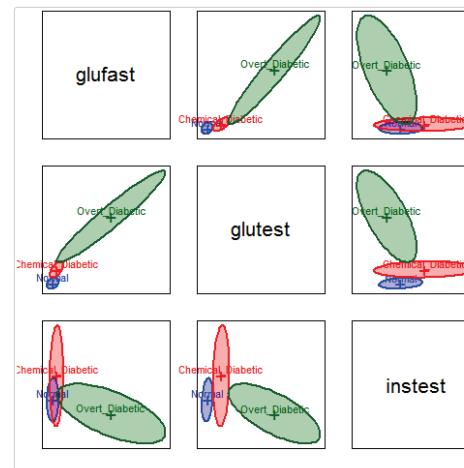

Using the first 3D computer graphics system (PRIM-9) they rotated the data in 3-space until a hypothesis was suggested.

43

## Diabetes data: Ellipses

```
covEllipses(Diabetes[2:5], Diabetes$group, fill=TRUE, pooled=FALSE,
            col=c("blue", "red", "darkgreen"), variables=1:3)
```

The pairwise data ellipses show visual summaries of the data

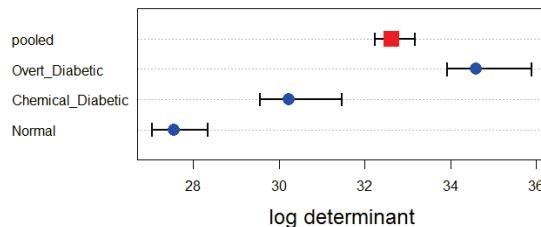

The differences in correlation and variances are dramatic here

44

## Box's $M$ test

```
diab.boxm <- boxM(Diabetes[,2:5], Diabetes$group)
diab.boxm
##
## Box's M-test for Homogeneity of Covariance Matrices
##
## data: Diabetes[, 2:5]
## Chi-Sq (approx.) = 383, df = 20, p-value <2e-16
plot(diab.boxm)
```

All pairs differ!

45

## Summary

- MANOVA tests of MLMs are easily visualized in HE plots
  - Contrasts among groups can be easily shown
  - Canonical plots show data in 2D/3D space of max. group differences
  - Robust methods can help guard against outliers
- MMRA models
  - Visualize effects of quant. predictors as lines in data space
  - Test & visualize any linear hypothesis
  - Canonical correlations: visualize in 2D/3D of max. (X, Y) correlations
- Homogeneity of covariances
  - Visualize within-group  $\mathbf{S}_i$  and pooled  $\mathbf{S}_p$  by data ellipses
  - Visualize Box's M test by simple dot plot of  $|\mathbf{S}_p|$  and  $|\mathbf{S}_i|$

46
